

# Lecture 17: Gauge fixing I

Jonathan Evans

22nd November 2011

Our aim today is to prove

### Theorem (Uhlenbeck)

*Consider the trivial  $U(n)$ -bundle over the unit 2-disc. There exist  $\kappa > 0$  and  $c < \infty$  such that if  $\nabla = d + A$  is a connection with  $\|F_\nabla\|_{L^2} \leq \kappa$  then there is an  $L^2_2$ -gauge transformation  $u$  such that  $u\nabla = d + A'$  satisfies*

- $d^*A' = 0$ ,
- $\|A'\|_{L^2_1} \leq c\|F_\nabla\|_{L^2}$ .

*Moreover if we require the boundary condition that the radial component  $\sum_i (x_i/r)A_i$  tends to zero as  $r \rightarrow 1$  then the resulting  $A'$  is unique up to constant gauge transformations.*

As when we proved that a unitary connection induces the structure of a holomorphic vector bundle, it will be convenient to work over a compact space so we use  $S^2$  instead of the 2-disc (in this we follow Donaldson-Kronheimer rather than Uhlenbeck's original proof).

### Theorem

*There are constants  $\zeta$  and  $N$  such that if  $\nabla_t = d + A_t$  is a path of connections on the trivial  $U(n)$ -bundle over  $S^2$  with  $A_0 = 0$  and  $\|F_{\nabla_t}\|_{L^2} \leq \zeta$  then there exist  $L^2_2$ -gauge transformations  $u_t$  such that  $u_t \nabla_t = d + A'_t$  satisfy  $d^* A'_t = 0$  and  $\|A'_t\|_{L^2_1} < 2N \|F_{\nabla_t}\|_{L^2}$  (unless  $A'_t = 0$ ).*

Let's write  $S \subset [0, 1]$  for the subset of the interval consisting of  $t$  for which the conclusion of the theorem holds.

To deduce Uhlenbeck's theorem from this we take our connection of interest  $\nabla$  over the disc and construct a connection on the sphere by pulling back along the map  $p$  which collapses the 2-sphere onto a disc (by projecting onto a plane through the equator). Obviously this is not smooth along the equator, so instead we take a sequence of smooth approximations  $p_\epsilon$  to  $p$  which differ only in an  $\epsilon$  neighbourhood of the equator. Now suppose  $\nabla$  has curvature  $L^2$ -bounded above by  $\zeta/\sqrt{2} - \epsilon'$ . Then for small enough  $\epsilon$ ,  $p_\epsilon^*\nabla$  has curvature  $L^2$ -bounded above by  $\zeta$ . Moreover we can define a path of connections  $\nabla_t$ ,  $t \in [0, 1]$  with  $\nabla_0 = d$  by setting  $A_t(x) = tA(tx)$  (here  $x \mapsto tx$  is just rescaling the ball).

Since

$$\begin{aligned}\|F_{\nabla_t}\|_{L^2} &= \sqrt{\int_{x \leq 1} |t^2 F_{\nabla}(tx)|^2 d\text{vol}_x} \\ &= \sqrt{\int_{y \leq t} t^4 t^{-2} |F_{\nabla}|^2 d\text{vol}_y} \\ &\leq t \|F_{\nabla}\|_{L^2} \\ &\leq \zeta/\sqrt{2} - \epsilon'\end{aligned}$$

we see that  $p_{\epsilon}^* \nabla_t$  is a path of connections satisfying the hypotheses of the theorem. This allows us to put  $\nabla$  in Coulomb gauge on a slightly smaller ball, but that's all we need.

The idea will be to prove that  $S$  is both closed and open. Since  $0 \in S$  the theorem will follow. First we prove a lemma.

### Lemma

*Let  $d + A$  be a connection on the trivial bundle over  $S^2$  such that  $d^*A = 0$ . Then there are constants  $N, \eta > 0$  such that*

$$\|A\|_{L^4} < \eta \implies \|A\|_{L^2_1} \leq N \|F_\nabla\|_{L^2}.$$

## Proof.

Since  $d$  is elliptic on  $\ker(d^*)$  (think about it! This is just ellipticity of the Laplacian) and since it has no kernel (otherwise there would be nontrivial harmonic 1-forms on  $S^2$  and hence a nontrivial class in  $H^1(S^2)$ ) we have

$$\|A\|_{L^2_1} \leq C\|dA\|_{L^2}$$

Since  $F_\nabla = dA + [A, A]$  and  $\|[A, A]\|_{L^2} \leq \|A\|_{L^4}^2 \leq C'\|A\|_{L^4}\|A\|_{L^2_1}$  by Hölder and Sobolev we get

$$\|A\|_{L^2_1} \leq C\|dA\|_{L^2} \leq C\|F\|_{L^2} + CC'\|A\|_{L^4}\|A\|_{L^2_1}$$

and when  $\|A\|_{L^4} < 1/(2CC') = \eta$  we can take the last term over to the other side and get

$$\|A\|_{L^2_1} \leq N\|F\|_{L^2}$$

(where  $N = 2C$ ).

Now we take  $\zeta < \frac{\eta}{2CN}$  where  $\eta$  and  $N$  are given by this lemma and  $C$  is the Sobolev constant for the embedding  $L_1^2 \subset L^4$ .

### Lemma

*Given a path satisfying the hypotheses of the theorem,  $S$  is closed.*

### Proof.

Let  $t_i \in S$  be a sequence converging to some  $t_\infty$  and write  $A_{t_i} = A_i$ , so that there exist gauge transformations  $u_i$  such that  $A'_i = u_i A_i$  satisfies the conclusions of the theorem. Certainly as  $i \rightarrow \infty$ ,  $A_i \rightarrow A_{t_\infty} = A_\infty$ . Since  $A'_i$  is bounded in  $L_1^2$  there is a weakly convergent subsequence  $A'_i \rightarrow A'_\infty$ . We want to construct an  $L_2^2$ -gauge transformation  $u_\infty$  from  $A_\infty$  to  $A'_\infty$ . But

$$A'_i = u_i^{-1} A_i u_i + u_i^{-1} du_i$$

i.e.  $du_i = u_i A'_i - A_i u_i$

## Proof, continued:

Since  $u_i(x) \in U(n)$  which is compact we have  $|u_i|_{L^2} \leq c$  and

$$|du_i|_{L^4} \leq c(|A'_i|_{L^4} + |A_i|_{L^4}) \leq cC(|A'_i|_{L^2_1} + |A_i|_{L^2_1})$$

Therefore  $|u_i|_{L^4_1}$  is bounded uniformly in  $i$  and hence weakly converges to some  $u$  in  $L^4_1$ . We need to show that  $u$  is in  $L^2_2$ , but we know that

$$du = uA' - Au$$

and now I'm going to do something I said I wouldn't, which is to use another Sobolev theorem I haven't previously stated. It follows from Palais "Foundations of Global Analysis", Theorem 9.5(2) that  $L^4_1 \otimes L^2_1 \rightarrow L^2_1$  is a well-defined Sobolev multiplication in 2-d. Therefore since  $u \in L^4_1$  and  $A, A' \in L^2_1$  we get  $du \in L^2_1$  and hence  $u \in L^2_2$ . □

## Proof.

The coclosedness equation is certainly preserved in the limit. It remains to show that the inequality (which is open!) is preserved. But if we know that  $s \in [0, 1]$  satisfies the hypotheses of the theorem then

$\|A'_s\|_{L^4} \leq C\|A'_s\|_{L^2_1} < 2NC\|F'_s\|_{L^2} \leq \eta$  by the choice of  $\zeta$  and hence by the lemma we first proved  $\|A'_s\|_{L^2_1} \leq N\|F'_s\|_{L^2}$ . This condition is closed and is strictly stronger than  $\|A_s\|_{L^2_1} < 2N\|F'_s\|_{L^2}$  hence the open condition is preserved in the limit. □
